Abstract: There are many problems in the field of science, engineering and technology which can be solved by differential equations formulation. The wave equation is a second order linear hyperbolic partial differential equation that describes the propagation of variety of waves, such as sound or water waves. In this paper we consider the convergence analysis of the explicit schemes for solving one dimensional, time-dependent wave equation with Drichlet and Neumann boundary condition. Taylor's series expansion is used to expand the finite difference approximations in the explicit scheme. We present the derivation of the schemes and develop a computer program to implement it. We use spectral radius of Matrix obtained from discretization and Von Neumann stability condition to determine stability, and consistence of the method from truncated error from discretized method. Using Lax Equivalence Theorem, convergence of the methods was described by testing consistency and stability of the methods. And it is found out that the scheme is stable with the Drichlet boundary and conditionally stable with Derivative boundary condition.

Keywords: Wave Equation, Explicit Method, Convergence, Stability

1. Introduction

The wave equation is a second order linear hyperbolic partial differential equation that describes the propagation of variety of waves, such as sound or water waves. It arises in different fields such as an acoustics, electromagnetic or fluid dynamics [6, 7]. In many situations finding analytic solutions to partial differential equation is unrealistic or even impossible. Numerical methods that utilize computer algorithms are then used to find approximate solution [2, 3, 10]. The focus of this paper is to determine the stability and convergence of finite difference schemes that approximates a solution of wave equation. Suppose that an elastic string of length $L$ is tightly stretched between two supports at the same horizontal level. So that the x-axis lies along the string. The elastic string may be thought of as violin sting, guy wire or possibly an electric power line. Suppose that the string is set in motion so it vibrates in vertical plane and let $u(x, t)$ denote the vertical displacement experienced by the string at the point $x$ at time $t$ if damping effects, such as air resistance are neglected. If the amplitude of the motion is not too large, then $u(x, t)$ satisfies the equation, $u_{tt} = c^2 u_{xx}$. On domain $0 < x < L, t > 0$ the equation is one dimensional wave equation. [11]

![Figure 1. A vibrating string.](image)

The coefficient $c^2$ in the equation is $c^2 = \frac{T}{m}$ where $T$ is the tension (force) in the string and $m$ is the mass per unit length of the string material. To describes the motion of the string completely it is necessary also to specify suitable initial and boundary conditions for displacement $u(x, t)$. The ends are assumed to remain fixed and therefore the boundary condition are $u(0, t) = 0$ and $u(L, t) = 0$ $t \geq 0$ since the wave
equation is of second order with respect to \( t \) is plausible to prescribe two initial conditions those are the initial position of the string \( u(x, 0) = f(x) \).

\( 0 \leq x \leq L \) And its initial velocity \( u_t(x, 0) = g(x) \), \( 0 \leq x \leq L \) where \( f \) and \( g \) are given functions. The finite difference methods are the techniques for numerical solution to the wave equation by the discretization of space and time.

Let the string in the deformed state coincide with the interval \([0, L]\) on the \( x \) axis, and let \( u(x, t) \) be the displacement at time \( t \) in the \( y \) direction of a point initially at \( x \). The displacement function \( u \) is governed by the mathematical model

\[
\frac{\partial^2 u}{\partial t^2} = c^2 \frac{\partial^2 u}{\partial x^2} + f(x, t) \quad x \in (0, L), t \in (0, T) \tag{1}
\]

(гoverning equation)

\[
u(0, t) = u(L, t) = 0 \quad \text{(Initial condition)} \tag{2}
\]

\[
u_t(0, t) = u_t(L, t) = 0 \quad \text{(Boundary condition)} \tag{3}
\]

Since this PDE Contains a second-order derivative in time, we need two initial conditions, here \( u(x, 0) = f(x) \), specifying the initial shape of the string, \( f(x) \), and \( \frac{\partial u(x,0)}{\partial t} = g(x) \). In addition, PDEs need boundary conditions, here \( u(0,t) = u(L,t) = 0 \), specifying that the string is fixed at the ends, that is, the Displacement \( u \) is zero. The solution \( u(x,t) \) varies in space and time and describes waves that are moving with velocity \( c \) to the left and right.

2. Finite Difference Methods

The finite difference techniques are based up on the approximations that permit replacing differential equation by finite difference equation. There finite difference approximations are algebraic in form, and the solutions are related to grid points. Thus, a finite difference solution basically involves three steps:

1. Dividing the solution into grids of notes.
2. Approximating the given differential equation by finite difference equivalence that relates the solutions to grid points.
3. Solving the difference equations subject to the prescribed boundary conditions and or Initial conditions. [2, 5, 9]

2.1. Explicit Finite Difference Method

The numerical solution of one dimensional wave equation using explicit scheme is obtained and the error calculated. To determine the stability and convergence, we will consider the simplified form of the wave equation (1) Common form.

\[
c^2 \frac{\partial^2 u}{\partial t^2} = \frac{\partial^2 u}{\partial x^2} + f(x, t) \quad \text{With the boundary condition } u(0, t) = u(L, t) = 0 \text{ And the initial condition } u(x, 0) = f(x), \text{ and } u_t(x,0) = g(x). \]

Using finite difference we have

\[
\frac{\partial^2 u}{\partial x^2} = \frac{u_{j+1,n} - 2u_{j,n} + u_{j-1,n}}{h^2} \tag{4}
\]

Substituting equations (4) and (5) into the equation (1) it is approximated by

\[
c^2 \frac{u_{j+1,n} - 2u_{j,n} + u_{j-1,n}}{h^2} = \frac{u_{j,n+1} - 2u_{j,n} + u_{j,n-1}}{h^2} \tag{5}
\]

Making \( u_{j,n+1} \) the subject and substituting \( r^2 = \frac{c^2 h^2}{k^2} \) we obtain

\[
u_{j,n+1} = (2 - 2r^2)u_{j,n} + r^2 u_{j+1,n} + r^2 u_{j-1,n} - u_{j,n-1} \tag{9}
\]

2.2. Matrix Form of Explicit Scheme

Referring to equation (1), we discretize in space, using \( n \) nodes the temperature at time \( j \Delta t \) is given by \([u]_j = u_j, u_{j+1}, u_{j+2}, \ldots, u_{j+n-1}]^T \) since \( u_1, j = 0 \) for all \( j \).

When grouped in values in rows and using \( r = \frac{ak}{h} \) Equation (9) can be rearranged to obtain

\[
u_{n+1} = \bar{u}_{n+1} = r^2 u_{j-1,n} + (2 - 2r^2)u_{j,n} + r^2 u_{j+1,n} - u_{j,n-1} \tag{10}
\]

The parameter \( r = \frac{ak}{h} > 0 \) depends up on wave speed and the ratio of space and time step size the boundary condition (1) Require that (2) this allow us to rewrite the system in matrix form

\[
\overline{u}_{n+1} = B\overline{u}_n - \overline{u}_{n-1} + b_l \tag{11}
\]

Where \( B = \begin{pmatrix}
2 (1 - r^2) & r^2 & \cdots & 0 \\
r^2 & 2 (1 - r^2) & \cdots & 0 \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & r^2 & 2 (1 - r^2)
\end{pmatrix} \) and

\[
\overline{u}_n = \begin{pmatrix}
u_{1,n} \\
\vdots \\
u_{j,n} \\
\vdots \\
u_{j-1,n}
\end{pmatrix}
\]

2.3. One Dimensional Wave Equation with Derivative Boundary Condition

The boundary condition \( u(x, t) = f(x) \) makes \( u \) change sign at the boundary, while the condition \( u_x(x, t) = 0 \) perfectly reflects the wave. Our next task is to determine the stability with boundary condition \( u_x(x, t) = 0 \) which is more complicated to express numerically. We shall present two methods for implementing \( u_x(x, t) = 0 \) in a finite difference scheme, one based on deriving a modified stencil at the boundary, and another one based on extending the mesh with ghost cells and ghost points.

Neumann boundary condition:

\[
\frac{\partial u}{\partial n} = n \cdot \nabla u = 0 \tag{12}
\]

The derivative \( \frac{\partial u}{\partial n} \) is in the outward normal direction from a general boundary.
For one dimension domain \([0; L]\), we have that:

\[
\frac{\partial u}{\partial t} \bigg|_{x=L} = \frac{\partial }{\partial x} \frac{\partial u}{\partial t} \bigg|_{x=0} = - \frac{\partial }{\partial x}
\]

Boundary conditions that specify the value of \(u_n\) are known as Neumann conditions, while refer to specifications of \(u\). When \(\frac{\partial u}{\partial n} = 0\) or \(u = 0\) it is Dirichler boundary condition.

The Discretization of derivatives at the boundary in the finite difference scheme is used central differences in all the other approximations to derivatives in the scheme, it is tempting to implement (12) at \(x = 0\) and \(t = t_n\) by the difference

\[
\frac{u_{-1,n} - u_{1,n}}{2\Delta x} = 0 \quad (13)
\]

The problem is that \(u_{-1,n}\) is not a \(u\) value that is being computed since the point is outside the mesh. However, if we combine (13) with the scheme for \(j = 0\),

2.4. Fourier Method (Von Neumann Stability)

Fourier stability analysis allows determining appropriate step sizes for an accurate solution when the wavelength or decay constant (which is given in terms of parameters such as a diffusion constant or wave velocity in the (PDE) has a certain value. Fourier stability analysis does not take boundary conditions for a specific problem into account. And it performed by substituting the analytic solution to a partial differential equation into the numerical finite difference equation. \([8, 12-14]\)

Assume \(u(x, t) = \sum_k \tilde{u}(k) \exp(ikx)\). The sum is over \(k\), the Fourier frequencies. Now take for \(u\) just one Fourier

Term \(u(x, t) = \tilde{u}(k) \exp(ikx)\) And evaluate it at \((x, t_n)\) to get

\[
\begin{align*}
    u_{j,n} &= \tilde{u}_n \exp(ikj\Delta x) \quad , \quad u_{j-1,n} = \tilde{u}_n \exp(ik(j-1)\Delta x) \quad , \\
    u_{j+1,n+1} &= \tilde{u}_{n+1} \exp(ik(j+1)\Delta x) \quad \text{and} \quad u_{j,n-1} = \tilde{u}_{n-1} \exp(ik(j-1)\Delta x)
\end{align*}
\]

These expressions can be plugged directly into any finite difference scheme to check for stability. The growth rate \(G\) is defined as \(G = \frac{\tilde{u}_{n+1} - \tilde{u}_n}{\Delta x}\) for stability we need \(G < 1\) for all frequencies \(k\). Conditional stability means we only have stability on a certain condition. Usually the condition limits \(\Delta t\) in function of \(\Delta x\)

2.5. Matrix Method to Determine Stability

The condition for stability of methods is determined by finding the spectral radius which is \(p(A) = \max (\lambda_i)\) where \(\lambda_i\) is an eigenvalue of matrix \(A\), as illustrated below.

(i) If \(p(A) < 1\) then the system is stable.
(ii) If \(p(A) < 1\) then the system is stable.
(iii) If \(p(A) > 1\) then the system is unstable.

Tridiagonal matrices are often found in connection with finite differences. Tridiagonal matrices are easy to deal with since there exists ancient numerical methods both for solving their linear systems of equations and eigenvalue problem. Here we consider the eigenvalue problem for a general tridiagonal matrix of the form \([1, 4, 13, 15]\)

Lax Equivalence theorem: The Lax-Richtmyer Equivalence Theorem is often called the Fundamental Theorem of Numerical Analysis, even though it is only applicable to the small subset of linear numerical methods for well-posed, linear partial differential equations. Along with Dahl Quist’s equivalence theorem for ordinary differential equations, the notion that the relationship consistency + stability ⇒ convergence always holds has caused a great deal of confusion in the numerical analysis of differential equations. In the case of PDEs, mathematicians are most often interested in nonlinear phenomena, for which Lax-Richtmyer does not apply. More damningly, the forward implication that

Consistent + stability ⇒ convergence

Theorem: Gerschgorin’s theorem: Consider a square matrix \(A = (a_{ij})\), for row \(i\) the disk \(D_i\) have centre \(a_{ii}\) and radius \(\sum_{j=1}^{n}|a_{ij}|\). Then the theorem states that;

Every eigenvalue of \(A\) lies in some \(D_i\).

If \(S\) is the union of \(s\) disks \(D_i\) such that \(S\) is disjoint from all other disks of this type, then \(S\) contains precisely \(m\) eigenvalues of \(A\).

3. Analysis of Convergence for Explicit Scheme

3.1. Consistency of the Explicit Method

The truncation error of the approximation of the time derivative is \(T_1\) given by

\[
\frac{\partial^2 u}{\partial t^2} = \frac{u_{j+1,n+1} - 2u_{j,n} + u_{j-1,n}}{\Delta t^2} + T_1 \quad \text{Where} \quad T_1 = -\frac{k^2}{\Delta x^2} (x, \eta)
\]

Where \(t-k < \eta < t + k\) from the Taylor series expansion. Similarly, for the space derivative,

\[
\frac{\partial^2 u}{\partial x^2} = \frac{u_{j+1,n} + u_{j-1,n} - 2u_{j,n}}{\Delta t^2} + T_2
\]

Where \(T_2 = -\frac{h^2}{\Delta x^2} (x, \xi)\) is the truncation error \(x - h \leq \xi \leq x + h\). Combining the two terms above \(\frac{\partial^2 u}{\partial t^2} - a^2 \frac{\partial^2 u}{\partial x^2} = 0\)

\[
\begin{align*}
    u_{j+1,n} - 2u_{j,n} + u_{j-1,n} &- a^2 \frac{u_{j+1,n} - 2u_{j,n} + u_{j-1,n}}{h^2} + T_r \\
    & = 0
\end{align*}
\]

Where \(T_r\) the truncation error \(T_r = T_1 - T_2 = -\frac{k^2}{\Delta t^2} u_{\xi \xi \xi \xi}(x, \eta) + \frac{h^2}{\Delta x^2} u_{\xi \xi \xi \xi}(x, \xi)\)

Where \(x - h \leq \xi \leq x + h\) and \(t-k < \eta < t + k\) it then follows that

\[
\left| T_r \right| \leq \frac{k^2}{\Delta t^2} M_{\xi \xi \xi \xi} + \frac{h^2}{\Delta x^2} M_{\xi \xi \xi \xi} = \frac{1}{12} (k^2 M_{\xi \xi \xi \xi} + h^2 M_{\xi \xi \xi \xi})
\]

Where \(M_{\xi \xi \xi \xi}\) is a bound for \(u_{\xi \xi \xi \xi}(x, \eta)\) and \(M_{\xi \xi \xi \xi}\) is a bound for \(u_{\xi \xi \xi \xi}(x, \xi)\).
3.2. Stability Analysis of Explicit Method

3.2.1. Stability For Explicit with Dirichlet Boundary Condition

The stability of this numerical scheme proceeds as follows

\[ u_{j,n+1} = (2 - 2r^2)u_{j,n} + r^2u_{j+1,n} + r^2u_{j-1,n} - u_{j,n-1} \]  \quad (14)

We first need to recast the second order iteration system (14) in to a fist order system

\[ \bar{u}_{n+1} = B \bar{u}_n - \bar{u}_{n-1} + b_i \]  \quad (15)

\[ \begin{pmatrix} \bar{u}_{n+1} \\ \bar{u}_n \\ \bar{u}_{n-1} \end{pmatrix} = \begin{pmatrix} B & -I \\ I & 0 \end{pmatrix} \begin{pmatrix} \bar{u}_n \\ \bar{u}_{n-1} \end{pmatrix} + b_i \]  \quad (16)

Let \( \tilde{Z}_{n+1} = \begin{pmatrix} \bar{u}_{n+1} \\ \bar{u}_n \end{pmatrix} \), \( \tilde{Z}_n = \begin{pmatrix} \bar{u}_n \\ \bar{u}_{n-1} \end{pmatrix} \) and \( C = \begin{pmatrix} B & -I \\ I & 0 \end{pmatrix} \)

Implies that

\[ \tilde{Z}_{n+1} = C\tilde{Z}_n + b_i \]  \quad (17)

Therefore the stability of the method will be determined by the Eigen value of the coefficient matrix \( C \) the Eigen vector equation \( Cz = \lambda z \) where \( z = \begin{pmatrix} u \\ v \end{pmatrix} \) can be written out in its individual components

\[ \begin{pmatrix} B & -I \\ I & 0 \end{pmatrix} \begin{pmatrix} u \\ v \end{pmatrix} = \lambda \begin{pmatrix} u \\ v \end{pmatrix} \]  \quad (18)

\[ Bu - v = \lambda u \]  \quad (19)

\[ u = \lambda v \]  \quad (20)

Substituting (20) into (19) we find

\[ (\lambda B - \lambda^2 - 1)v = 0 \quad Or \quad Bv = (\lambda + \frac{1}{\lambda})v \]  \quad (21)

The latter equation implies that \( v \) is the Eigen vector of \( B \) with \( \lambda + \lambda^{-1} \) the corresponding Eigen values of the tridiagonal matrix \( B \)

\[ \left( \lambda + \frac{1}{\lambda} \right) = 2 \left( 1 - r^2 + r^2 \cos \frac{\pi k}{n} \right) \quad k = 1, 2, N-1 \]  \quad (22)

Multiplying both sides of equation (22) by \( \lambda \) leads to a quadratic equation for the Eigen values let \( a_k = 1 - r^2 + r^2 \cos \frac{\pi k}{n} \)

\[ \lambda^2 - 2a_k \lambda + 1 = 0 \]  \quad (23)

Where \( a_k \) must be less than or equal to \( -1 \) and \( \lambda \) complex number of modules 1, indicated stability of the matrix \( C \) [7]

Therefore in view of \( 1 - 2r^2 < a_k < 1 \) we should require that

\[ r = \frac{ck}{h} < 1 \quad Or \quad k < \frac{h}{c} \]  \quad (23)

This places a restriction on the relative sizes of the time and space steps. We conclude that the numerical scheme is conditionally stable. The stability criterion (23) is known as the Courant condition. The Courant condition requires that the mesh slope, which is defined to be the ratio of the space step size to the time step size, namely \( h/k \), must be strictly greater than the characteristic slope \( c \)

3.2.2. Stability of the Explicit Method with Derivative Boundary Condition

The difference equation that we will use to time stepping the numerical scheme

\[ u_x(1,n) = 0 \quad Left \ boundary \quad j = 1, n = 1, \ldots, M \]  \quad (24)

\[ u_x(N,n) = 0 \quad Right \ boundary \quad j = N, n = 1, \ldots, M \]  \quad (25)

\[ u_{j+1,n} = u_{j-1,n} \quad Derivative \ boundary \quad for \ j = 0 \]  \quad (26)

\[ u_{j-1,n} = u_{j+1,n} \quad Derivative \ boundary \quad for \ j = N \]  \quad (27)

\[ u_{j,1} = f_j \quad Row \ 1 = 2, \ldots, N - 1 \quad n = 1 \]  \quad (28)

\[ u_{j,2} = f_j + gjk + r^2 (f_{j+1} - 2f_j + f_{j-1}) \quad Row \ 2 = 2, N - 1 \]  \quad \( n = 2 \)  \quad (29)

We can eliminate the fictitious value \( u_{j-1,n} \) from (16), which can be used in (21) to arrive at a modified scheme for the boundary point \( u_{0,n+1} \)

\[ u_{j,1} = (2 - 2r^2)u_{j,n} + r^2 (u_{j+1,n} + u_{j-1,n}) - u_{j,n-1} \]  \quad (30)

Similarly, if it applied at \( x = N \) is discretized by using (31) we have

\[ u_{j,N-1} = (2 - 2r^2)u_{j,n} + r^2 (u_{j+1,n} + u_{j-1,n}) - u_{j,n-1} \]  \quad (31)

We have the explicit scheme with derivative boundary is

\[ u_{j,n+1} = (2 - 2r^2)u_{j,n} + 2r^2 u_{j+1,n} - u_{j,n-1} \quad for \ j = 0 \]  \quad (33)

\[ u_{j,n+1} = (2 - 2r^2)u_{j,n} + 2r^2 (u_{j+1,n} + u_{j-1,n}) - u_{j,n-1} \]  \quad (34)

\[ u_{j,n+1} = (2 - 2r^2)u_{j,n} + 2r^2 u_{j+1,n} - u_{j,n-1} \]  \quad for \( j = N \)  \quad (35)

Its matrix form is as follows

\[ \tilde{u}_{n+1} = A\tilde{u}_n + \tilde{d} + b_i \]  \quad (36)

Where \( A = \begin{pmatrix} 2 - 2r^2 & 2r^2 & \cdots & 0 \\ r^2 & 2 - 2r^2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & \cdots & \cdots & 2r^2 - 2r^2 \end{pmatrix} \)
\[
\bar{u}_{n+1} = A \bar{u}_n + \bar{c} \quad \text{where} \quad \bar{c} = \bar{d} + \bar{b}
\]

This is significant result in that it shows that the vector \( \bar{c} \) does not affect stability.

For stability \( p(A) \leq 1 \). Consider the matrix \( A = \begin{pmatrix} 2 - 2r^2 & 2r^2 & \cdots & 0 \\ r^2 & 2 - 2r^2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & \cdots & 2r^2 & 2 - 2r^2 \end{pmatrix} \)

The disks for row 2 to \( N - 1 \) have center \( 2 - 2r^2 \) and radii \( 2r^2 \) so the eigenvalue lies in \( 2 - 2r^2 - 2r^2 \leq \lambda \leq 2 - 2r^2 + 2r^2 \)

\[
2 - 4r^2 \leq \lambda \leq 2
\]

\[
2 - 4r^2 \geq -1 \quad \text{which implies that} \quad r \leq \frac{\sqrt{3}}{2}
\]

Consider the first and last row with center \( 2 - 2r^2 \) and radii \( 2r^2 \) The disk

\[
2 - 2r^2 - 2r^2 \quad 2 - 2r^2 \quad 2 - 2r^2 + 2r^2
\]

\( p(A) \leq 1 \) If \( 2 - 4r^2 \geq -1 \) and 2 so the explicit scheme is stable for \( r \leq \frac{\sqrt{3}}{2} \).

This shows that with derivative boundary condition the explicit scheme stability depends on the values of \( r \).

4. Numerical Experiment

Numerical examples are presented to verify stability and convergence of the method.

Example 1 Use the explicit scheme to solve the one dimensional wave equation

\[
u_{tt} = 4u_{xx} \quad 0 \leq x \leq 1, 0 \leq t \leq 1
\]

\[
u_x(0, t) = \cos(2t), \quad u_x(\pi, t) = -\cos(2t) \quad \text{and} \quad u(x, 0) = \sin(x), \quad u_x(x, 0) = 0
\]

Example 2. Use the explicit scheme to solve the one dimensional wave equation

\[
u_{tt} = 4u_{xx} \quad \text{For} \quad x \in [0, L] \quad t \in [0, T] \quad \text{With boundary condition} \quad u(0, t) = u(L, t) = 0 \quad \text{Initial distribution is} \quad u(x, 0) = \sin(rx) \quad \text{and} \quad u_t(x, 0) = 0
\]
5. Discussion and Conclusion

5.1. Discussion

I used one dimensional wave equation by considering the space domain to have a length of M that is \( u_{tt} = c^2 u_{xx} + f(x, t) \) with dirichlet and derivative boundary conditions. The explicit finite differences were considered. To determine its stability by Von Neumann stability condition and Eigen value of tridiagonal matrix obtained from discretized scheme of the equation was used to develop the analysis. To produce values for the problem variable finite difference mesh point were used for the space domain. A mat lab code was written for explicit methods with dirichlet and derivative boundary condition.

The numerical scheme is said to be stable when an error is introduced at certain stage, then remains bounded as time approaches infinity. It so happen that the error propagates in the same way as the problem variable, so an unstable process can be observed by the solution growing beyond any bounds. With small \( r \) the method performed well. The explicit scheme has an advantage that it is easy to set up, and disadvantage that it is unstable for \( r \) greater than one with dirichlet and unstable for \( r \leq \sqrt{\frac{3}{2}} \) with derivative boundary.

5.2. Conclusion

This study has considered the explicit finite difference schemes for solving one dimensional time dependent wave equation with dirichlet and Neumann boundary conditions. The difference schemes are derived. Using Lax Equivalence Theorem convergence of the method was described by testing consistency and stability of the methods. Stability was discussed by using Gerschgorin’s Theorem and Von Neumann stability condition. And the stability of the Explicit method is shown by the table below.

<table>
<thead>
<tr>
<th>Methods</th>
<th>Dirchlet</th>
<th>Derivative</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explicit scheme</td>
<td>stable ( r \leq 1 )</td>
<td>conditionally stable ( r \leq \sqrt{\frac{3}{2}} )</td>
</tr>
</tbody>
</table>

In the above table the Dirchlet boundary condition are \( u(0, t) = u(L, t) = 0 \) and the derivative boundary condition are \( u(x, t) = f(x), u_x(x, t) = g(x) \) 1 is the critical value such that for \( r \leq 1 \) scheme is stable.

A systematic study was applied to the two test numerical problems and the schemes have been successfully applied. The performance of the schemes for the considered problems was measured by calculating the error.
